API Operations Guide

Day 8 RAG practice document

1. Authentication

Every API request must include an Authorization header containing a valid bearer token. Tokens expire after 60 minutes. Clients should request a new token when they receive an authentication error.

2. Rate Limits

The standard plan allows 100 requests per minute per account. When the limit is exceeded, the API returns HTTP 429. Clients should wait before retrying and use exponential backoff.

3. Retries

Retry network timeouts and temporary server errors such as HTTP 502, 503, and 504. Do not repeatedly retry validation errors or other permanent 4xx responses. Use an idempotency key for operations that create payments or orders.

4. Pagination

List endpoints return at most 50 records per page. Use the next_cursor value from the response to request the next page. Stop when next_cursor is null.

5. Monitoring

Record request ID, endpoint, response status, latency, and retry count. Never log access tokens, passwords, or full payment card details.
